PROJECTION FACTORS FOR MILK AND FAT LACTATION RECORDS

By George R. Wiggans and Rex L. Powell ^{1/}

Factors to estimate 305-day production have been derived. The production on the last sample day is the primary information to estimate the production from the end of the partial record until 305 days. For records of 155 or fewer days, the mature equivalent herd average is also required. This average is computed from records of cows in the same herd that freshened 1 to 2 years prior to the last sample day of the record. The herd average increases the accuracy of the projection by providing information on the normal production level of the herd.

For both milk and fat, a separate set of factors is provided for each of the four month-of-freshening periods, two parity groups, three regions (for Holstein, Jersey, and Guernsey as shown in fig. 1), and five breeds. For Ayrshire and Brown Swiss there is only one region. Jersey factors are used for Milking Shorthorn and Holstein factors are used for all other breeds.

Data

Sample-day milk and fat production records from the New York, North Carolina, Iowa, Wisconsin, and Utah Dairy Records Processing Centers for cows freshening in 1973 and 1974 were used to calculate the factors. Records were eliminated for the following reasons: Fewer than 180 days in milk, more than 55 days before the first sample day, no dry date (if less than 305 days in milk), more than 40 days from last sample day until the end of the record, more than 60 days between sample days, a sample-day milk production less than 1 pound or greater than 150 pounds, a sample-day fat percent less than 1.5 or greater than 9.0, any sample day reported as abnormal, or less than 18 months or greater than 96 months of age at freshening. These edits removed unusual records and records with important information missing.

Cumulative production through each sample day and for 305 days was computed for each record using adjustments to the early and last test intervals.

Because of the large number of Holstein records, only every 10th record was considered. The numbers of lactation records used to compute the regional factors for milk and fat for the five breeds follow:

^{1/} Research geneticists (animal), Animal Improvement Programs Laboratory, Animal Science Institute, Beltsville Agricultural Research Center, Beltsville, Md. 20705.

	<u>North</u>	<u>South</u>	<u>West</u>	<u>Total</u>
Ayrshire ^{1/} -----	-----	-----	-----	20,192
Guernsey-----	23,255	14,738	12,132	50,125
Holstein-----	81,014	27,536	38,568	147,118
Jersey-----	27,926	22,085	9,113	59,124
Brown Swiss ^{1/} -----	-----	-----	-----	12,425

^{1/} No regions were defined for these breeds.

Records of other breeds were not used to compute the factors but were used to assess suitability.

Application of Factors

The factors in tables 1-11 are applied as illustrated in this example of an Ayrshire cow in first lactation that freshened in December with a record in progress of 44 days in milk (DIM), and with production to date of 1,800 pounds of milk and 40 pounds on day 44. The herd average is 13,000 pounds. This average should be divided by 1,000 for use with the factors in the tables. The computations (* = multiply) are as follows:

$$\text{Projected 305-day record } (\hat{Y}_{305}) = \text{Partial record } (Y_{\text{DIM}}) +$$

[estimated average daily production] * (days remaining)

$$\hat{Y}_{305} = Y_{\text{DIM}} + [(\text{intercept} + \text{slope} * \text{DIM}) * \text{sample-day production} + (\text{intercept} + \text{slope} * \text{DIM}) * \text{herd average}] * (305 - \text{DIM})$$

$$\hat{Y}_{305} = 1,800 + [(0.443 + 0.00315 * 44) * 40 + (1.419 + (-0.01666) * 44) * 13] * (305 - 44)$$

$$\hat{Y}_{305} = 1,800 + [0.5816 * 40 + 0.686 * 13] * 261$$

$$\hat{Y}_{305} = 1,800 + [23.26 + 8.92] * 261 = 10,199$$

For records of more than 155 days, the herd average is not used. The following example illustrates the same cow with 8,000 pounds of milk at 200 days and 35 pounds on the 200th day.

$$\hat{Y}_{305} = Y_{\text{DIM}} + [(\text{intercept} + \text{slope} * \text{DIM}) * \text{sample-day production} + (\text{intercept} + \text{slope} * \text{DIM}) * (305 - \text{DIM})]$$

$$\hat{Y}_{305} = 8,000 + [(0.355 + 0.0026 * 200) * 35 + 10.853 + (-0.06785) * 200] * (305 - 200)$$

$$\hat{Y}_{305} = 8,000 + [30.62 - 2.72] * 105 = 10,930$$

Special Handling Procedures

Last sample day not at end of record.--Terminated records usually do not end on a sample day, therefore an adjustment is made to the last sample-day production to estimate production at the end of the record. This adjustment uses the Shook factors for the interval from the last sample to the end of lactation. The adjusted sample-day production = $(2 * \text{factor} - 1) * \text{last sample-day production}$. This method accounts for the additional days milked after the last sample day.

Abnormal sample day.--A sample day reported abnormal is not used. The most recent normal sample day is used to project the record after adjustment as described previously.

Low milk production on last sample day.--A floor (minimum value) is provided so that last sample-day production below the floor is set equal to the floor value before being used in the equation. The floor value is 10 pounds through 100 days in milk and $(13.6 - 0.035 * \text{DIM})$ pounds thereafter.

High milk production on last sample day.--Last sample-day production exceeding twice the average daily production of the partial record and greater than 75 pounds is considered abnormal and is not used.

Abnormal percent fat on last sample day.--Restrictions were imposed to improve the projected fat records by constraining unusual values. The last sample-day percent fat is set equal to the percent fat of the partial record (PF) - 1.5 if it is less than PF - 1.5 or set equal to PF + 2.5 if it is greater than PF + 2.5.

Floor for projected record.--The estimated average daily production for the remainder of the lactation is set equal to $0.6 * \text{last sample-day production}$ if it falls below this value. Without this restriction, a negative prediction of remaining production would be possible when last sample-day production is low. This can occur because of the negative values of some of the coefficients.

Conclusions

These factors provide improved estimates of 305-day production because additional information is used to project records. This system accounts for season of freshening, region, production level of the herd, and production on the last sample day of the record. The sample-day production information is restricted so that the projected record is within reasonable bounds. Except for the change in the equation at 155 days in milk, there is a smooth change in the factors by days in milk so that factors for a given day are similar to those for adjoining days.

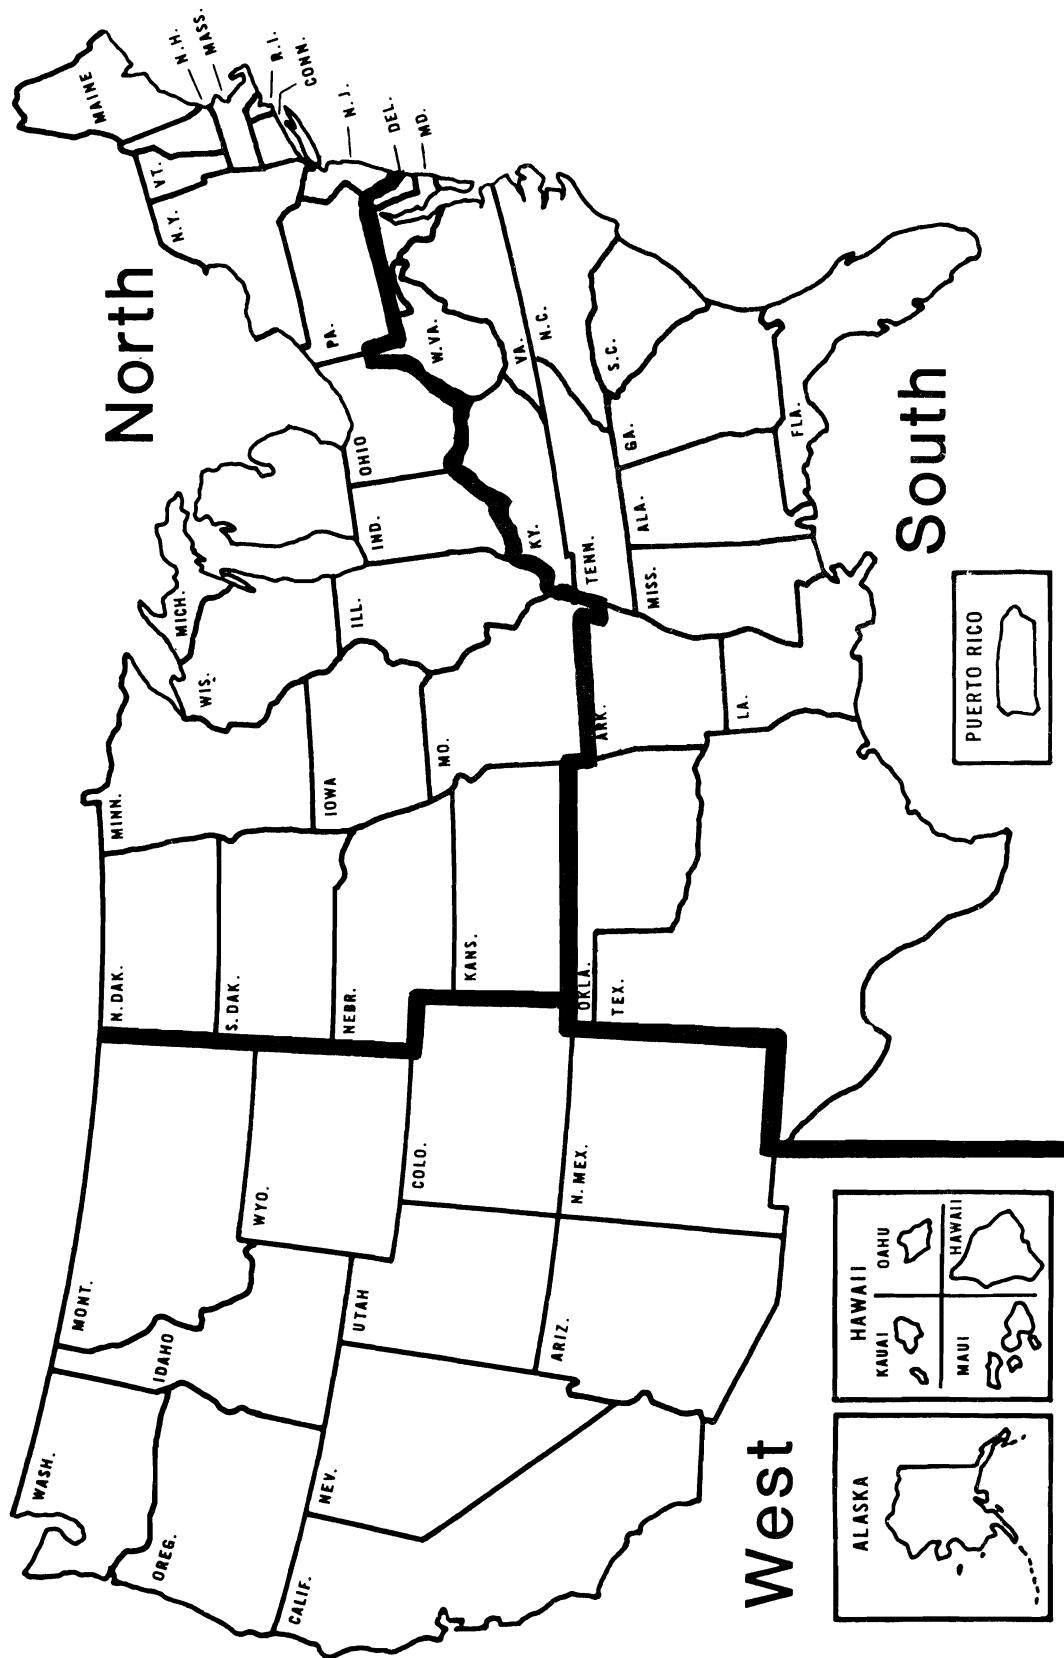

Figure 1.--Regions for projection factors.
